new Expressions

The execution of a new expression takes two steps:

1. Allocate a block of memory.
2. Construct the object(s) on the allocated memory.

What we can control is the first step.

operator new

Memory allocation is done by a group of functions:

```cpp
// Not inlined, not in any namespace
void *operator new(std::size_t size);
void *operator new[](std::size_t size);
```

- For `new Type(args)`, the memory is allocated by calling `operator new(sizeof(Type))`.

- For `new Type[n]{initializers}`, the memory is allocated by calling `operator new[](sizeof(Type) * n)`.

* C++17 alignment-aware allocation? Talk later.

new/delete in Modern C++
○○○○○○
○○○○○○
○○○

operator new

```
void *operator new(std::size_t size);
void *operator new[](std::size_t size);
```

- These two functions **do not know** the type of object(s) to be created.
- `operator new[]` **does not know** the number of objects to be created.

delete Expressions

The execution of a `delete` expression takes two steps:

1 Destroy the object. (Not executed by C++20 destroying-delete)

2 Deallocate the memory.

What we can control is the second step.

new Expressions and operator new

new/delete in Modern C++
○○○○○○
○○○○○○
○○○

operator delete

Memory deallocation is done by a group of functions:

```
// Not inlined, not in any namespace
void operator delete(void *ptr) noexcept;
void operator delete[](void *ptr) noexcept;
```

- `delete ptr` deallocates the memory by calling
  `operator delete(ptr)`.

- `delete[] ptr` deallocates the memory by calling
  `operator delete[](ptr)`.

* C++14 sized-deallocation? Talk later.

operator delete

Exceptions are not welcomed!

- All deallocation functions are noexcept, unless specified otherwise in the declaration.
- If a deallocation function terminates by throwing an exception, the behavior is **undefined**, even if it is declared with noexcept(false).
  - Such exception is not expected to be caught. Stack is possibly not unwound in this case.

Standard Library Version

Standard `operator new`

The following functions are *replacable*:

```cpp
void *operator new(std::size_t size);
void *operator new[](std::size_t size);
void operator delete(void *ptr) noexcept;
void operator delete[](void *ptr) noexcept;
```

- Standard versions (normal versions) are defined in standard library file `<new>`.
- But the compiler will choose the user-defined version if there exists one.
- In this case, they do not constitute redefinition.

                                  0000000   000000
                                                                                   000

Standard Library Version

Standard operator new

Difference between operator new and malloc?
Basic:

- operator new allocates some memory when `size == 1`,
  while the behavior of `malloc(0)` is implementation-defined.
- On failure, operator new throws std::bad_alloc, while
  malloc returns null pointer.

new Expressions and operator new   **Overloading operator new**   Placement-new   new/delete in Modern C++
000000   000●00   0000000   000000
                                    0000000   000000   000000
                                                                                        000

Standard Library Version

Standard operator new

A simple operator new that uses malloc for allocation:

```
void *operator new(std::size_t size) {
  if (size == 0)
    size = 1;
  if (auto ptr = std::malloc(size))
    return ptr;
  throw std::bad_alloc{};
}
```

(Similar for operator new[]...)

new Expressions and operator new   **Overloading operator new**   Placement-new   new/delete in Modern C++

                                       ooooooo   oooooo   oooooo
                                                                                            ooo

Standard Library Version

Standard `operator new`

In fact, `operator new` keeps trying to allocate memory and, on failure, does some possible adjustment by calling a **new-handler**, until the allocation succeeds or no new-handler is available.

```
void *operator new(std::size_t size) {
  if (size == 0)
    size = 1;
  while (true) {
    if (auto ptr = std::malloc(size))
      return ptr;
    auto handler = std::get_new_handler();
    if (handler)
      handler();
    else
      throw std::bad_alloc{};
  }
}
```

                                                                                   ooo

Standard Library Version

Standard `operator delete`

Possible implementation of `operator delete` that uses `std::free` to deallocate memory:

```cpp
void operator delete(void *ptr) noexcept {
  std::free(ptr);
}
```

- Make sure it is safe to `delete` a null pointer.
- Similar for `operator delete[]`.

Overloading

Why Overload them?

Effective C++ Item 50 talks about the following most common reasons:

- To detect usage errors.
- To improve efficiency.
- To collect usage statistics.

Overloading

Record Allocations

```cpp
void *operator new(std::size_t size) {
  if (size == 0)
    size = 1;
  while (true) {
    if (auto ptr = std::malloc(size)) {
      recorder.add_record(ptr);
      return ptr;
    }
    auto handler = std::get_new_handler();
    if (handler)
      handler();
    else
      throw std::bad_alloc{};
  }
}
```

Overloaded and Customized new/delete

new/delete in Modern C++
000000
000000
000

Overloading

Class-specific Versions

```
struct Widget {
  static void *operator new(std::size_t size);
  static void *operator new[](std::size_t size);
  static void operator delete(void *ptr);
  static void operator delete[](void *ptr);
};
```

- When we use new/new[] to create class-type objects, the lookup for operator new/operator new[] begins in the class scope.

- If the new-expression uses the form `::new`, the class-scope lookup is **bypassed** and the global version `::operator new` / `::operator new[]` will be called.

new Expressions and operator new   **Overloading operator new**   Placement-new   new/delete in Modern C++
000000   000000   0000000   000000
                                    0000000●0   000000   000000
                                                                                     000

Overloading

Class-specific Versions

```cpp
struct Widget {
  static void *operator new(std::size_t size);
  static void *operator new[](std::size_t size);
  static void operator delete(void *ptr);
  static void operator delete[](void *ptr);
};
```

- The keyword `static` is optional: these functions are always static members.
- Deallocation functions are implicitly `noexcept`.

Overloading

Example: `Heap_tracked`

This example is from *More Effective C++* Item 27: Requiring or prohibiting heap-based objects.

- `dynamic_cast<const void *>(ptr)` yields the beginning address of the object. (Casting it to `void *`, `volatile void *` or `const volatile void *` also work.)
- Track whether an object is heap-based by inheriting `Heap_tracked` in a **mixin** style.

Customized Versions

Placement-`delete`

Recall the two steps for a `new` expression:

1 Allocate enough memory.

2 Construct the object(s).

For a `new` expression `new (args...) Type(ctor_args...)`, if an exception is thrown during the **second** step:

- The corresponding `operator delete` is called with `ptr, args...` passed to it, where `ptr` is the beginning location of memory allocated in the first step.

- The `operator delete` deallocates the memory allocated by `operator new` to ensure memory-safety and exception-safety.

Placement-delete

Possible implementation for non-throwing `new`:

```cpp
void operator delete(void *ptr,
                     const std::nothrow_t &) noexcept {
  ::operator delete(ptr);
}
```

Placement-`delete`

Possible implementation for the real "placement-`new`"?

```cpp
void operator delete(void *, void *) noexcept {}
void operator delete[](void *, void *) noexcept {}
```

Notice
If no suitable placement-`delete` is found, no deallocation function would be called, which possibly results in memory leak.

Placement-delete

Which `operator delete` is called?

```
auto ptr = new (std::nothrow) Type(args);
delete ptr;
```

Answer: **the normal version with no extra arguments.** A placement-`delete` is called only when constructors throw an exception.

Sized-delete

For some kinds of deallocation functions, it might be necessary to
know the **size** of the block of memory to be deallocated.
A deallocation function which receives an extra std::size_t
parameter is a **sized-deallocation function**.

Notice
Sized-deallocation function is a **usual** deallocation function. It is
not a placement version.

Sized-delete

Sized-delete

Before C++14, sized-delete could only be class-scoped static member:

```cpp
struct Widget {
  int x;
  static void operator delete(void *p, std::size_t sz) {
    std::cout << "size == " << sz << '\n';
    ::operator delete(p);
  }
};
auto ptr = new Widget;
delete ptr;
```

Output:

```
size == 4
```

                                           0000000   000000   000000
                                                                                                     000

Sized-delete

Sized-delete

Before C++14, sized-delete could only be class-scoped static member:

```cpp
struct Widget {
  int x;
  static void operator delete[](void *p, std::size_t sz) {
    std::cout << "size == " << sz << '\n';
    ::operator delete[](p);
  }
};
auto ptr = new Widget[100];
delete []ptr;
```

Possible output:

```
size == 408
```

                                    0000000   000000   000000
                                                                                   000

Sized-delete

Sized-delete

If a sized-deallocation function is defined and its corresponding
unsized version is not, the sized version is called for a
delete-expression to deallocate the memory.

- The std::size_t argument is passed by the compiler
  automatically.

new Expressions and operator new   Overloading operator new   Placement-new   new/delete in Modern C++
000000   000000   0000000   000000
                                   0000000   000000   000000
                                                                               000

Sized-delete

Sized-delete

If a sized-deallocation function is defined and its corresponding
unsized version is not, the sized version is called for a
delete-expression to deallocate the memory.

- The std::size_t argument is passed by the compiler
  automatically.

Since C++14, global sized-deallocation functions are also allowed:

```cpp
void operator delete(void *ptr, std::size_t size) noexcept;
void operator delete[](void *ptr, std::size_t size) noexcept;
```

new Expressions and operator new   Overloading operator new   Placement-new   new/delete in Modern C++

                                   0000000   000000   000000
                                                                               000

Sized-delete

Sized-delete

The compiler may choose to call the sized version **or** the unsized one.

- Clang-14 calls the unsized version by default, even when the sized version is provided.
- Calls to one version must be effectively equivalent to the other version, otherwise the program has undefined behavior.
- The standard library implementations of sized-deallocation functions directly call the unsized versions.

Alignment-aware new/delete

Alignment of Objects

Every object type has the **alignment requirement** property,
representing the number of bytes between successive addresses at
which objects of this type can be allocated.

- Alignment requirement of an object is an integer value of type
  std::size_t, and is always a power of 2.
- Alignment requirement could be queried with alignof or
  std::alignment_of.

                                                                                  000

Alignment-aware new/delete

Alignment-aware Allocation

Since C++17, a group of alignment-aware allocation functions are introduced:

```cpp
void *operator new(std::size_t size, std::align_val_t al);
void *operator new[](std::size_t size, std::align_val_t al);
void *operator new(std::size_t size,
     std::align_val_t al, const std::nothrow_t &) noexcept;
void *operator new[](std::size_t size,
     std::align_val_t al, const std::nothrow_t &) noexcept;
```

(Together with their deallocation functions and sized-deallocation functions.)

- `<cstdlib>` also introduces `std::aligned_alloc`.

                                    ooooooo   oooooo   ooooo●
                                                                                    ooo

Alignment-aware new/delete

Alignment-aware Allocation

```
namespace std {
  enum class align_val_t : size_t {};
}
```

- Normal allocation functions allocate objects aligned at
  __STDCPP_DEFAULT_NEW_ALIGNMENT__ (might be 16).
- If `alignof(Type)` exceeds the default `new` alignment, the
  `new`-expression calls the alignment-aware `operator new` and
  passes `alignof(Type)` as the second argument. (Similar for
  array-`new`.)
